(November 17, 2023)

## 1 Problem

The image method arose in electrostatics,<sup>1</sup> and in general cannot be applied to time-dependent examples because the boundary conditions for  $\mathbf{E}$  and  $\mathbf{B}$  are not satisfied at the relevant perfectly conducting surface. Show, however, that image method does apply to arbitrary time-dependent charge/current distributions above a perfectly conducting plane.

## 2 Solution

We recall that the boundary conditions at the surface of a perfect conductor are that the electric field  $\mathbf{E}$  be perpendicular to the surface, while the magnetic field  $\mathbf{B}$  must be parallel to the surface.

We consider an electric charge  $q$  in arbitrary motion above a perfectly conducting plane, say,  $z = 0$ . In the absence of the conducting plane, the electromagnetic fields of the charge are those given by Liénard and Wiechert [3, 4], which can be written as,

$$\mathbf{E} = q \left( \frac{\hat{\mathbf{r}} - \boldsymbol{\beta}}{\gamma^2(1 - \hat{\mathbf{r}} \cdot \boldsymbol{\beta})^3 r^2} \right) + \frac{q}{c} \left( \frac{\hat{\mathbf{r}} \times ((\hat{\mathbf{r}} - \boldsymbol{\beta}) \times \dot{\boldsymbol{\beta}})}{(1 - \hat{\mathbf{r}} \cdot \boldsymbol{\beta})^3 r} \right), \quad \mathbf{B} = \hat{\mathbf{r}} \times \mathbf{E}, \quad (1)$$

in Gaussian units, where  $\mathbf{r}$  is the distance vector from the charge to the observation point,  $\boldsymbol{\beta} = \mathbf{v}/c$  is the velocity of the charge normalized to  $c$ , the speed of light in vacuum,  $\dot{\boldsymbol{\beta}} = d\boldsymbol{\beta}/dt$  is the normalized acceleration,  $\gamma = 1/\sqrt{1 - \beta^2}$ , and  $\mathbf{r}$ ,  $\boldsymbol{\beta}$  and  $\dot{\boldsymbol{\beta}}$  are evaluated at the retarded time  $t_{\text{ret}} = t - r/c$ .

To verify the boundary conditions at the surface,  $z = 0$ , of the perfectly conducting plane, we now consider an observation point on that plane.

Writing  $\mathbf{r} = \mathbf{r}_{\perp} + \mathbf{r}_z$ ,  $\boldsymbol{\beta} = \boldsymbol{\beta}_{\perp} + \boldsymbol{\beta}_z$  and  $\dot{\boldsymbol{\beta}} = \dot{\boldsymbol{\beta}}_{\perp} + \dot{\boldsymbol{\beta}}_z$ , the corresponding quantities for the image charge  $q' = -q$  with respect to the plane  $z = 0$  can be written as  $\mathbf{r}' = \mathbf{r}_{\perp} - \mathbf{r}_z$ ,  $\boldsymbol{\beta}' = \boldsymbol{\beta}_{\perp} - \boldsymbol{\beta}_z$  and  $\dot{\boldsymbol{\beta}}' = \dot{\boldsymbol{\beta}}_{\perp} - \dot{\boldsymbol{\beta}}_z$ . Then,  $\hat{\mathbf{r}}' \cdot \boldsymbol{\beta}' = \hat{\mathbf{r}} \cdot \boldsymbol{\beta}$ ,  $\beta' = \beta$  and  $\gamma' = \gamma$ , so we can write the electric fields  $\mathbf{E}$  (due to  $q$ ) and  $\mathbf{E}'$  (due to image charge  $-q$ ) for  $z = 0$  as,

$$\begin{aligned} \mathbf{E}(z = 0) &= a(\hat{\mathbf{r}} - \boldsymbol{\beta}) + b(\hat{\mathbf{r}} \times ((\hat{\mathbf{r}} - \boldsymbol{\beta}) \times \dot{\boldsymbol{\beta}})) \\ &= a(\hat{\mathbf{r}} - \boldsymbol{\beta}) + b(\hat{\mathbf{r}} \cdot \dot{\boldsymbol{\beta}})(\hat{\mathbf{r}} - \boldsymbol{\beta}) - b(1 - \hat{\mathbf{r}} \cdot \boldsymbol{\beta})\dot{\boldsymbol{\beta}} \\ &= a(\hat{\mathbf{r}}_{\perp} + \hat{\mathbf{r}}_z - \boldsymbol{\beta}_{\perp} - \boldsymbol{\beta}_z) + b(\hat{\mathbf{r}} \cdot \dot{\boldsymbol{\beta}})(\hat{\mathbf{r}}_{\perp} + \hat{\mathbf{r}}_z - \boldsymbol{\beta}_{\perp} - \boldsymbol{\beta}_z) - b(1 - \hat{\mathbf{r}} \cdot \boldsymbol{\beta})(\dot{\boldsymbol{\beta}}_{\perp} + \dot{\boldsymbol{\beta}}_z), \end{aligned} \quad (2)$$

$$\begin{aligned} \mathbf{E}'(z = 0) &= -a(\hat{\mathbf{r}}' - \boldsymbol{\beta}') - b(\hat{\mathbf{r}}' \times ((\hat{\mathbf{r}}' - \boldsymbol{\beta}') \times \dot{\boldsymbol{\beta}}')) \\ &= -a(\hat{\mathbf{r}}_{\perp} - \hat{\mathbf{r}}_z - \boldsymbol{\beta}_{\perp} + \boldsymbol{\beta}_z) - b(\hat{\mathbf{r}} \cdot \dot{\boldsymbol{\beta}})(\hat{\mathbf{r}}_{\perp} - \hat{\mathbf{r}}_z - \boldsymbol{\beta}_{\perp} + \boldsymbol{\beta}_z) - b(1 - \hat{\mathbf{r}} \cdot \boldsymbol{\beta})(\dot{\boldsymbol{\beta}}_{\perp} - \dot{\boldsymbol{\beta}}_z), \end{aligned} \quad (3)$$

---

<sup>1</sup>The image method was first discussed by W. Thomson (Lord Kelvin) in 1848 [1]. For a review that mentions the present problem, see [2].

where function  $a$  (and function  $b$ ) has the same value at a point on the surface of the conducting plane for both charge  $q$  and image charge  $-q$ . Hence, the total electric field at the surface of the conducting plane is,

$$\mathbf{E}_{\text{tot}}(z = 0) = \mathbf{E}(z = 0) + \mathbf{E}'(z = 0) = 2a(\hat{\mathbf{r}}_z - \boldsymbol{\beta}_z) + 2b(\hat{\mathbf{r}} \cdot \dot{\boldsymbol{\beta}})(\hat{\mathbf{r}}_z - \boldsymbol{\beta}_z) - 2b(1 - \hat{\mathbf{r}} \cdot \boldsymbol{\beta})\dot{\boldsymbol{\beta}}_z, \quad (4)$$

which has only a  $z$ -component, as required at the surface of a perfect conductor.

The magnetic fields at the surface of the perfect conductor are, recalling eqs. (2)-(3).

$$\mathbf{B}(z = 0) = \hat{\mathbf{r}} \times \mathbf{E} = -a\hat{\mathbf{r}} \times \boldsymbol{\beta} - b(\hat{\mathbf{r}} \cdot \dot{\boldsymbol{\beta}})\hat{\mathbf{r}} \times \boldsymbol{\beta} - b(1 - \hat{\mathbf{r}} \cdot \boldsymbol{\beta})\hat{\mathbf{r}} \times \dot{\boldsymbol{\beta}}, \quad (5)$$

$$\mathbf{B}'(z = 0) = \hat{\mathbf{r}}' \times \mathbf{E}' = a\hat{\mathbf{r}}' \times \boldsymbol{\beta}' + b(\hat{\mathbf{r}} \cdot \dot{\boldsymbol{\beta}})\hat{\mathbf{r}}' \times \boldsymbol{\beta}' + b(1 - \hat{\mathbf{r}} \cdot \boldsymbol{\beta})\hat{\mathbf{r}}' \times \dot{\boldsymbol{\beta}}'. \quad (6)$$

Now,

$$\hat{\mathbf{r}} \times \boldsymbol{\beta} = (\hat{r}_y\beta_z - \hat{r}_z\beta_y)\hat{\mathbf{x}} + (\hat{r}_z\beta_x - \hat{r}_x\beta_z)\hat{\mathbf{y}} + (\hat{r}_x\beta_y - \hat{r}_y\beta_x)\hat{\mathbf{z}}, \quad (7)$$

$$\hat{\mathbf{r}}' \times \boldsymbol{\beta}' = -(\hat{r}_y\beta_z - \hat{r}_z\beta_y)\hat{\mathbf{x}} - (\hat{r}_z\beta_x - \hat{r}_x\beta_z)\hat{\mathbf{y}} + (\hat{r}_x\beta_y - \hat{r}_y\beta_x)\hat{\mathbf{z}}, \quad (8)$$

since  $\mathbf{r} = r_x\hat{\mathbf{x}} + r_y\hat{\mathbf{y}} + r_z\hat{\mathbf{z}}$  and  $\boldsymbol{\beta} = \beta_x\hat{\mathbf{x}} + \beta_y\hat{\mathbf{y}} + \beta_z\hat{\mathbf{z}}$ , while  $\mathbf{r}' = r_x\hat{\mathbf{x}} + r_y\hat{\mathbf{y}} - r_z\hat{\mathbf{z}}$  and  $\boldsymbol{\beta}' = \beta_x\hat{\mathbf{x}} + \beta_y\hat{\mathbf{y}} - \beta_z\hat{\mathbf{z}}$ . Then,

$$\hat{\mathbf{r}} \times \boldsymbol{\beta} - \hat{\mathbf{r}}' \times \boldsymbol{\beta}' = 2(\hat{r}_y\beta_z - \hat{r}_z\beta_y)\hat{\mathbf{x}} + 2(\hat{r}_z\beta_x - \hat{r}_x\beta_z)\hat{\mathbf{y}}, \quad (9)$$

and similarly for  $\hat{\mathbf{r}} \times \dot{\boldsymbol{\beta}} - \hat{\mathbf{r}}' \times \dot{\boldsymbol{\beta}}'$ , both of which have no  $z$ -component. Hence, the total magnetic field  $\mathbf{B}_{\text{tot}}(z = 0) = \mathbf{B}(z = 0) + \mathbf{B}'(z = 0)$  at the surface of the conducting plane has no  $z$ -component, as required at the surface of a perfect conductor.

Thus, the image method is valid for a single electric charge with arbitrary motion above a perfectly conducting plane. And, via the superposition principle, this also holds for any charge/current distribution above an infinite, perfectly conducting plane.

However, for arbitrary, time-dependent motion of the charge, the electromagnetic-field boundary conditions cannot be satisfied for any other type of surface of a perfect conductor, and the time-dependent image method does not in general.

### 3 Comments

The time-dependent image method has its main application to antennas over a perfectly conducting “ground” plane, to which the surface of the Earth is a good-enough approximation in many places.<sup>2</sup> This was discussed in [7, 8] for “electric” dipole antennas parallel and perpendicular to the “ground” surface. These examples were reviewed by the author in [9] for both “electric” and “magnetic” antennas. The more practical case of antennas above an imperfectly conducting plane has been discussed extensively, with approximate image methods reviewed, for example, in [10].

Another application of the time-dependent image method concerns current-carrying wires and metallic strips parallel to a perfectly conducting plane. These systems can be considered as 2-conductor transmission lines, with one of the conductors being the image (with respect to the perfectly conducting plane) of the physical wire/strip.

This note was inspired by e-discussions with Li Pan.

---

<sup>2</sup>Maxwell discussed a time-dependent image method for electric currents above an infinite conducting plane in 1872 [5], and in Arts. 660-667 of his *Treatise* [6].
